# A DIOPHANTINE INEQUALITY WITH FOUR SQUARES AND ONE $k$ TH POWER OF PRIMES 

Quanwu Mu, Minhui Zhu, Ping Li, Xi'an

Received July 3, 2017. Published online November 19, 2018.

Abstract. Let $k \geqslant 5$ be an odd integer and $\eta$ be any given real number. We prove that if $\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \mu$ are nonzero real numbers, not all of the same sign, and $\lambda_{1} / \lambda_{2}$ is irrational, then for any real number $\sigma$ with $0<\sigma<1 /(8 \vartheta(k))$, the inequality

$$
\left|\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right|<\left(\max _{1 \leqslant j \leqslant 5} p_{j}\right)^{-\sigma}
$$

has infinitely many solutions in prime variables $p_{1}, p_{2}, \ldots, p_{5}$, where $\vartheta(k)=3 \times 2^{(k-5) / 2}$ for $k=5,7,9$ and $\vartheta(k)=\left[\left(k^{2}+2 k+5\right) / 8\right]$ for odd integer $k$ with $k \geqslant 11$. This improves a recent result in W. Ge, T. Wang (2018).

Keywords: Diophantine inequalities; Davenport-Heilbronn method; prime

## 1. Introduction

In 1937, Vinogradov [23] proved that every sufficiently large odd integer is a sum of three primes. Later, Hua [11] refined Vinogradov's result and showed that all sufficiently large odd integers are sums of two primes and a $k$ th power of a prime, where $k$ is any given positive integer. In [11], Hua also proved that all sufficiently large odd integers satisfying some necessary congruence conditions can be represented

[^0]in the form of four squares of primes and a $k$ th power of a prime. It is of some interest to consider the analogous form for Diophantine inequalities. Some authors obtained many significant results in this direction, see [1], [2], [6], [8], [9], [13], [14], [15], [16], [19], [20], [21] for details. In [14], Li and Wang established the following theorem.

Theorem 1.1. Let $k \geqslant 3$ be a fixed integer and $\eta$ be any given real number. Suppose that $\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \mu$ are nonzero real numbers, not all of the same sign, and $\lambda_{1} / \lambda_{2}$ is irrational. Then the inequality

$$
\begin{equation*}
\left|\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right|<\left(\max _{1 \leqslant j \leqslant 5} p_{j}\right)^{-\sigma} \tag{1.1}
\end{equation*}
$$

has infinitely many solutions in prime variables $p_{1}, p_{2}, \ldots, p_{5}$ for $0<\sigma<1 /\left(3 k 2^{k}\right)$.
In [17], we improved the above result and showed that under the same assumptions as in Theorem 1.1, inequality (1.1) has infinitely many solutions in prime variables $p_{1}, p_{2}, \ldots, p_{5}$, where $0<\sigma<1 / 16$ for $k=3,0<\sigma<5 /\left(3 k 2^{k}\right)$ for $4 \leqslant k \leqslant 5$, and $0<\sigma<40 /\left(21 k 2^{k}\right)$ for $k \geqslant 6$. The proof is based on the method of Languasco and Zaccagnini in [12], together with Heath-Brown's improvement on Hua's lemma (see [4], Lemma 5 and [10], Theorem 2). Let

$$
s(k)=\left[\frac{k+1}{2}\right], \quad \sigma(k)=\min \left(2^{s(k)-1}, \frac{1}{2} s(k)(s(k)+1)\right),
$$

where $[x]$ denotes the largest integer not exceeding the real number $x$. Very recently, Ge and Wang [6] refined the result in [17]. They proved that under the same assumptions as in Theorem 1.1, inequality (1.1) has infinitely many solutions in prime variables $p_{1}, p_{2}, \ldots, p_{5}$ for $0<\sigma<1 /(8 \sigma(k))$ (see [6], Theorem 1.3).

The aim of the present paper is to further enlarge the range $0<\sigma<1 /(8 \sigma(k))$ for odd integer $k$ with $k \geqslant 5$. The following theorem is proved.

Theorem 1.2. Let $k \geqslant 5$ be an odd integer. Suppose that $\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \mu$ and $\eta$ satisfy the same conditions as in Theorem 1.1. Then for any real number $\sigma$ with $0<\sigma<1 /(8 \vartheta(k))$, inequality (1.1) has infinitely many solutions in prime variables $p_{1}, p_{2}, \ldots, p_{5}$, where

$$
\vartheta(k)= \begin{cases}3 \times 2^{(k-5) / 2} & \text { if } k=5,7,9,  \tag{1.2}\\ {\left[\left(k^{2}+2 k+5\right) / 8\right]} & \text { if } k \geqslant 11 \text { and } 2 \nmid k .\end{cases}
$$

With the help of Corollary 3.2 below, we obtain a wider major arc, this with the very recent work of Bourgain (see [3], Theorem 10) yields the desired conclusion.

## 2. Notation and preliminaries

The proof of Theorem 1.2 is dependent on the Davenport-Heilbronn circle method (see [22], Chapter 11). For each integer $j \geqslant 2$ set

$$
\psi(j)= \begin{cases}2^{j} & \text { when } 2 \leqslant j \leqslant 4  \tag{2.1}\\ j(j+1) & \text { when } j \geqslant 5\end{cases}
$$

In what follows, we use $\varepsilon$ and $\delta$ to denote fixed positive constants which are arbitrarily small. The letter $p$, with or without subscript, always stands for a prime number. The letter $k$, except as specially provided, usually denotes an odd integer not less than 5 . Since $\lambda_{1} / \lambda_{2}$ is irrational, we let $q$ be a large enough denominator of a convergent to $\lambda_{1} / \lambda_{2}$. Put

$$
\begin{aligned}
& X=q^{2}, \quad \mathcal{N}(X)= \\
& \tau \sum_{\substack{\delta X \leqslant p_{j}^{2} \leqslant X, 1 \leqslant j \leqslant 4, \delta X \leqslant p_{5}^{k} \leqslant X \\
\left|\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right|<\tau}} 1, \\
& S_{j}(\alpha)=X_{\delta X \leqslant p^{j} \leqslant X}^{-1 /(16 \vartheta(k))+30 \varepsilon}, \quad K_{\tau}(\alpha)= \begin{cases}\left(\frac{\sin (\pi \tau \alpha)}{\pi \alpha}\right)^{2} & \text { when } \alpha \neq 0, \\
\tau^{2} & \text { when } \alpha=0,\end{cases} \\
& I(\tau, \eta, \mathfrak{X})=\int_{\mathfrak{X}} \prod_{j=1}^{4} S_{2}\left(\lambda_{j} \alpha\right) S_{k}(\mu \alpha) e(\alpha \eta) K_{\tau}(\alpha) \mathrm{d} \alpha,
\end{aligned}
$$

where $e(\alpha)=\mathrm{e}^{2 \pi \mathrm{i} \alpha}, \mathfrak{X}$ denotes any measurable subset of $\mathbb{R}$ and $\vartheta(k)$ is defined by (1.2). For the Dirichlet kernel $K_{\tau}(\alpha)$ we have the trivial estimate

$$
\begin{equation*}
K_{\tau}(\alpha) \ll \min \left(\tau^{2},|\alpha|^{-2}\right) \tag{2.2}
\end{equation*}
$$

It follows from Lemma 4 of Davenport and Heilbronn [5] that

$$
\begin{equation*}
\int_{-\infty}^{\infty} e(x y) K_{\tau}(x) \mathrm{d} x=\max (0, \tau-|y|) \tag{2.3}
\end{equation*}
$$

Thus,

$$
\begin{align*}
& \mathcal{N}(X) \geqslant \frac{1}{\tau} \sum_{\substack{\delta X \leqslant p_{j}^{2} \leqslant X \\
1 \leqslant j \leqslant 4 \\
\delta X \leqslant p_{5}^{k} \leqslant X}} \max \left(0, \tau-\left|\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right|\right)  \tag{2.4}\\
& \geqslant \frac{1}{\tau(\log X)^{5}} \sum_{\substack{ \\
\delta X \leqslant p_{j}^{2} \leqslant X \\
1 \leqslant j 4 \\
\delta X \leqslant p_{5}^{k} \leqslant X}} \prod_{j=1}^{5} \log p_{j} \\
& \times \max \left(0, \tau-\left|\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right|\right) \\
&= \frac{1}{\tau(\log X)^{5}} \sum_{\substack{\delta X \leqslant p_{j}^{2} \leqslant X \\
1 \leqslant j 4 \\
\delta X \leqslant p_{5}^{k} \leqslant X}} \prod_{j=1}^{5} \log p_{j} \\
& \times \int_{-\infty}^{\infty} e\left(\left(\lambda_{1} p_{1}^{2}+\lambda_{2} p_{2}^{2}+\lambda_{3} p_{3}^{2}+\lambda_{4} p_{4}^{2}+\mu p_{5}^{k}+\eta\right) \alpha\right) K_{\tau}(\alpha) \mathrm{d} \alpha \\
& \tau(\log X)^{5} \\
& I(\tau, \eta, \mathbb{R}) .
\end{align*}
$$

To prove Theorem 1.2, it suffices to establish the estimate $I(\tau, \eta, \mathbb{R}) \gg \tau^{2} X^{1+1 / k}$. For this purpose, we split the real line into three parts

$$
\mathfrak{M}=\{\alpha:|\alpha| \leqslant \varphi\}, \quad \mathfrak{m}=\{\alpha: \varphi<|\alpha| \leqslant \xi\}, \quad \mathfrak{t}=\{\alpha:|\alpha|>\xi\},
$$

where $\varphi=X^{-1 /(2 k)-\varepsilon}, \xi=\tau^{-2} X^{3 \varepsilon}$. Usually, these sets are called the major arc, the minor arcs and the trivial arcs, respectively. Therefore

$$
\begin{equation*}
I(\tau, \eta, \mathbb{R})=I(\tau, \eta, \mathfrak{M})+I(\tau, \eta, \mathfrak{m})+I(\tau, \eta, \mathfrak{t}) \tag{2.5}
\end{equation*}
$$

It should be noted that the major arc $\mathfrak{M}$ is wider than that of [6]. In what follows, we shall show that

$$
|I(\tau, \eta, \mathfrak{M})| \gg \tau^{2} X^{1+1 / k}, \quad|I(\tau, \eta, \mathfrak{m})| \ll \tau^{2} X^{1+1 / k-\varepsilon}, \quad|I(\tau, \eta, \mathfrak{t})| \ll \tau^{2} X^{1+1 / k-\varepsilon} .
$$

Let $\mathbf{M}=\left\{\alpha:|\alpha| \leqslant X^{-1+5 /(6 k)-\varepsilon}\right\}$, then $\mathbf{M} \subset \mathfrak{M}$. In [17], Section 3, we have proved that

$$
\begin{equation*}
|I(\tau, \eta, \mathbf{M})| \gg \tau^{2} X^{1+1 / k} \tag{3.1}
\end{equation*}
$$

The conditions ' $\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}, \mu$ are nonzero real numbers, not all of the same sign' play an important role in the proof of (3.1), see [17], pages 485-486 for details. It remains to discuss the estimate for $|I(\tau, \eta, \mathfrak{M} \backslash \mathbf{M})|$.

Lemma 3.1 (see [7], Theorem 1). Let $j$ be an integer with $j \geqslant 2$, and $N \geqslant 2$. Suppose that $a$ and $q$ are integers with

$$
\begin{equation*}
|q \alpha-a| \leqslant \frac{1}{q}, \quad(a, q)=1, \quad q \geqslant 1 \tag{3.2}
\end{equation*}
$$

Then for any $\varepsilon>0$,

$$
\begin{equation*}
\sum_{p \leqslant N}(\log p) e\left(\alpha p^{j}\right) \ll N^{1+\varepsilon}\left(\frac{1}{q}+\frac{1}{N^{1 / 2}}+\frac{q}{N^{j}}\right)^{4^{1-j}} \tag{3.3}
\end{equation*}
$$

Corollary 3.2. Suppose that $X^{-1+5 /(6 k)-\varepsilon} \leqslant|\alpha| \leqslant X^{-1 /(2 k)-\varepsilon}$. Then for any given nonzero real $\mu$ and $\varepsilon>0$ we have

$$
\begin{equation*}
\left|S_{k}(\mu \alpha)\right| \ll X^{1 / k\left(1-1 / 2 \times 4^{1-k}\right)+\varepsilon} \tag{3.4}
\end{equation*}
$$

The implicit constant in the $\ll$ notation depends on $k, \mu, \delta$.
Proof. Notice that

$$
\begin{equation*}
\left|S_{k}(\mu \alpha)\right| \leqslant\left|\sum_{p \leqslant X^{1 / k}}(\log p) e\left(\mu \alpha p^{k}\right)\right|+\left|\sum_{p \leqslant(\delta X)^{1 / k}}(\log p) e\left(\mu \alpha p^{k}\right)\right| \tag{3.5}
\end{equation*}
$$

Similarly to [9], Corollary 2, we take $\mu \alpha$ in place of $\alpha$ in (3.2), and take $q=[1 /|\mu \alpha|]$, $a= \pm 1$ (the sign of $a$ is the same as that for $\mu \alpha$ ), then (3.4) follows from (3.5) and (3.3).

By Corollary 3.2 and the arithmetic-geometric mean inequality, we get

$$
\begin{align*}
&|I(\tau, \eta, \mathfrak{M} \backslash \mathbf{M})|  \tag{3.6}\\
& \leqslant \int_{\mathfrak{M} \backslash \mathbf{M}}\left|S_{2}\left(\lambda_{1} \alpha\right) S_{2}\left(\lambda_{2} \alpha\right) S_{2}\left(\lambda_{3} \alpha\right) S_{2}\left(\lambda_{4} \alpha\right) S_{k}(\mu \alpha)\right| K_{\tau}(\alpha) \mathrm{d} \alpha \\
& \ll \tau^{2} \max _{\alpha \in \mathfrak{M} \backslash \mathbf{M}}\left|S_{k}(\mu \alpha)\right| \sum_{j=1}^{4} \int_{\mathfrak{M} \backslash \mathbf{M}}\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{4} \mathrm{~d} \alpha \\
& \ll \tau^{2} X^{1 / k\left(1-1 / 2 \times 4^{1-k}\right)+\varepsilon} \int_{0}^{1}\left|S_{2}(\alpha)\right|^{4} \mathrm{~d} \alpha \\
& \ll \tau^{2} X^{1+1 / k-\varepsilon}
\end{align*}
$$

where (2.2) and Hua's lemma (see [4], page 85) are used. Noting that $I(\tau, \eta, \mathfrak{M})=$ $I(\tau, \eta, \mathbf{M})+I(\tau, \eta, \mathfrak{M} \backslash \mathbf{M})$, this with (3.1) and (3.6) implies

$$
\begin{equation*}
|I(\tau, \eta, \mathfrak{M})| \gg \tau^{2} X^{1+1 / k} \tag{3.7}
\end{equation*}
$$

## 4. The minor arcs

Let $\widetilde{\mathfrak{m}}=\mathfrak{m}_{1} \cup \mathfrak{m}_{2}$, where

$$
\mathfrak{m}_{j}=\left\{\alpha \in \mathfrak{m}:\left|S_{2}\left(\lambda_{j} \alpha\right)\right| \leqslant X^{7 / 16+2 \varepsilon}\right\} \quad \text { for } j=1,2
$$

To estimate the integral $I(\tau, \eta, \mathfrak{m})$, we need several lemmas.

Lemma 4.1. Let $j$ and $s$ be positive integers with $s \leqslant j$. Then

$$
\begin{equation*}
\int_{0}^{1}\left|S_{j}(\alpha)\right|^{s(s+1)} \mathrm{d} \alpha \ll X^{s^{2} / j+\varepsilon} \tag{4.1}
\end{equation*}
$$

holds for all $\varepsilon>0$.
Proof. It follows from [3], Theorem 10 that

$$
\begin{equation*}
\int_{0}^{1}\left|\sum_{\delta X \leqslant x^{j} \leqslant X} e\left(\alpha x^{j}\right)\right|^{s(s+1)} \mathrm{d} \alpha \ll X^{s^{2} / j+\varepsilon} . \tag{4.2}
\end{equation*}
$$

By considering the number of solutions of the underlying Diophantine equation and using (4.2), we obtain (4.1).

Lemma 4.2. Let $j \geqslant 2$ be an integer. Suppose that $\lambda$ and $\mu$ are nonzero real constants and $k$ is an odd integer with $k \geqslant 5$. Then for any $\varepsilon>0$ we have

$$
\begin{align*}
& \int_{\mathbb{R}}\left|S_{j}(\lambda \alpha)\right|^{\psi(j)} K_{\tau}(\alpha) \mathrm{d} \alpha \ll \tau X^{\psi(j) / j-1+\varepsilon}  \tag{4.3}\\
& \int_{\mathbb{R}}\left|S_{2}(\lambda \alpha)\right|^{2}\left|S_{k}(\mu \alpha)\right|^{2 \vartheta(k)} K_{\tau}(\alpha) \mathrm{d} \alpha \ll \tau X^{2 \vartheta(k) / k+\varepsilon}, \tag{4.4}
\end{align*}
$$

where $\psi(j)$ and $\vartheta(k)$ are defined by (2.1) and (1.2), respectively. The implicit constant in the $\ll$ notation of (4.3) depends on $\lambda, j$, and the implicit constant in the $\ll$ notation of (4.4) depends on $k, \lambda, \mu$.

Proof. For (4.3), see [18], Lemma 4.5 for details. It remains to prove (4.4). Let $a=(k-1) / 2, b=(k+1) / 2$.

We first consider the case of $k \geqslant 11,2 \nmid k$, recalling that $\vartheta(k)=\left[\left(k^{2}+2 k+5\right) / 8\right]$ in this case. When $k \equiv 1(\bmod 4)$, we have

$$
\vartheta(k)=\frac{k^{2}+2 k+5}{8}=\frac{a(a+1)+b(b+1)}{4}+\frac{1}{2} .
$$

It follows from the Cauchy-Schwarz inequality and Lemma 4.1 that

$$
\begin{align*}
& \int_{0}^{1}\left|S_{k}(\alpha)\right|^{2 \vartheta(k)} \mathrm{d} \alpha \ll X^{1 / k} \int_{0}^{1}\left|S_{k}(\alpha)\right|^{(a(a+1)+b(b+1)) / 2} \mathrm{~d} \alpha  \tag{4.5}\\
& \ll X^{1 / k}\left(\int_{0}^{1}\left|S_{k}(\alpha)\right|^{a(a+1)}\right)^{1 / 2}\left(\int_{0}^{1}\left|S_{k}(\alpha)\right|^{b(b+1)}\right)^{1 / 2} \\
& \ll X^{1 / k}\left(X^{a^{2} / k+\varepsilon}\right)^{1 / 2}\left(X^{b^{2} / k+\varepsilon}\right)^{1 / 2} \\
& \ll X^{\left(k^{2}+5\right) /(4 k)+\varepsilon} \ll X^{2 \vartheta(k) / k-1 / 2+\varepsilon}
\end{align*}
$$

where the trivial upper bound $S_{k}(\alpha) \ll X^{1 / k}$ is used. When $k \equiv 3(\bmod 4)$, we have

$$
\vartheta(k)=\frac{(k+1)^{2}}{8}=\frac{a(a+1)+b(b+1)}{4} .
$$

By a similar argument as that in (4.5), we also obtain

$$
\begin{equation*}
\int_{0}^{1}\left|S_{k}(\alpha)\right|^{2 \vartheta(k)} \mathrm{d} \alpha \ll X^{2 \vartheta(k) / k-1 / 2+\varepsilon} \tag{4.6}
\end{equation*}
$$

It follows from (2.3) that

$$
\begin{equation*}
\int_{\mathbb{R}}\left|S_{2}(\lambda \alpha)\right|^{2}\left|S_{k}(\mu \alpha)\right|^{2 \vartheta(k)} K_{\tau}(\alpha) \mathrm{d} \alpha \ll \tau \Sigma \tag{4.7}
\end{equation*}
$$

where $\Sigma$ denotes the number of solutions of

$$
\left|\mu\left(p_{1}^{k}+\ldots+p_{\vartheta(k)}^{k}-p_{\vartheta(k)+1}^{k}-\ldots-p_{2 \vartheta(k)}^{k}\right)+\lambda\left(p_{2 \vartheta(k)+1}^{2}-p_{2 \vartheta(k)+2}^{2}\right)\right|<\tau
$$

with $p_{i}^{k} \in[\delta X, X]$ for $1 \leqslant i \leqslant 2 \vartheta(k)$, and $p_{j}^{2} \in[\delta X, X]$ for $2 \vartheta(k)+1 \leqslant j \leqslant$ $2 \vartheta(k)+2$. Note that $\tau \rightarrow 0$ as $X \rightarrow \infty$. When $p_{2 \vartheta(k)+1} \neq p_{2 \vartheta(k)+2}$, the values of $p_{1}, p_{2}, \ldots, p_{2 \vartheta(k)}$ determine the values of $p_{2 \vartheta(k)+1}$ and $p_{2 \vartheta(k)+2}$ with at most $X^{\varepsilon}$ possibilities; these solutions contribute $\ll X^{2 \vartheta(k) / k+\varepsilon}$ to $\Sigma$. When $p_{2 \vartheta(k)+1}=p_{2 \vartheta(k)+2}$, we get

$$
\begin{equation*}
p_{1}^{k}+\ldots+p_{\vartheta(k)}^{k}-p_{\vartheta(k)+1}^{k}-\ldots-p_{2 \vartheta(k)}^{k}=0 . \tag{4.8}
\end{equation*}
$$

By (4.5) and (4.6), it follows that equation(4.8) has $O\left(X^{2 \vartheta(k) / k-1 / 2+\varepsilon}\right)$ solutions in primes $p_{1}, p_{2}, \ldots, p_{2 \vartheta(k)}$. In this case, these solutions also contribute $\ll X^{2 \vartheta(k) / k+\varepsilon}$ to $\Sigma$. Thus, we get $\Sigma \ll X^{2 \vartheta(k) / k+\varepsilon}$; this with (4.7) yields (4.4).

In the cases of $k=5,7,9$, noting that $\vartheta(k)=3 \times 2^{(k-5) / 2}=2^{a-2}+2^{b-2}$, we can also prove (4.6) using the Cauchy-Schwarz inequality and Hua's lemma. In a similar manner as above, we can prove (4.4). This completes the proof of Lemma 4.2.

From the arithmetic-geometric mean inequality, Hölder's inequality and Lemma 4.2, we get

$$
\begin{aligned}
I\left(\tau, \eta, \mathfrak{m}_{1}\right) \ll & \sum_{j=2}^{4} \int_{\mathfrak{m}_{1}}\left|S_{2}\left(\lambda_{1} \alpha\right)\right|\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{3}\left|S_{k}(\mu \alpha)\right| K_{\tau}(\alpha) \mathrm{d} \alpha \\
\ll & \left(\sup _{\alpha \in \mathfrak{m}_{1}}\left|S_{2}\left(\lambda_{1} \alpha\right)\right|\right)^{1 / \vartheta(k)}\left(\int_{\mathbb{R}}\left|S_{2}\left(\lambda_{1} \alpha\right)\right|^{4} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 / 4-1 /(2 \vartheta(k))} \\
& \times\left(\int_{\mathbb{R}}\left|S_{2}\left(\lambda_{1} \alpha\right)\right|^{2}\left|S_{k}(\mu \alpha)\right|^{2 \vartheta(k)} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 /(2 \vartheta(k))} \\
& \times \sum_{j=2}^{4}\left(\int_{\mathbb{R}}\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{4} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{3 / 4} \\
\ll & \left(X^{7 / 16+2 \varepsilon}\right)^{1 / \vartheta(k)}\left(\tau X^{1+\varepsilon}\right)^{1 / 4-1 /(2 \vartheta(k))}\left(\tau X^{2 \vartheta(k) / k+\varepsilon}\right)^{1 /(2 \vartheta(k))}\left(\tau X^{1+\varepsilon}\right)^{3 / 4} \\
\ll & \tau X^{1+1 / k-1 /(16 \vartheta(k))+4 \varepsilon} \ll \tau^{2} X^{1+1 / k-\varepsilon} .
\end{aligned}
$$

By symmetry, the same bound holds for $\mathfrak{m}_{2}$ in place of $\mathfrak{m}_{1}$. This implies that

$$
\begin{equation*}
I(\tau, \eta, \tilde{\mathfrak{m}}) \ll \tau^{2} X^{1+1 / k-\varepsilon} . \tag{4.9}
\end{equation*}
$$

It therefore remains to discuss the set $\mathfrak{m}^{*}=\mathfrak{m} \backslash \widetilde{\mathfrak{m}}$, in which

$$
\left|S_{2}\left(\lambda_{1} \alpha\right)\right|>X^{7 / 16+2 \varepsilon}, \quad\left|S_{2}\left(\lambda_{2} \alpha\right)\right|>X^{7 / 16+2 \varepsilon}, \quad X^{-1 /(2 k)-\varepsilon}<|\alpha| \leqslant \tau^{-2} X^{3 \varepsilon}
$$

hold simultaneously. By a familiar dyadic dissection argument, we divide $\mathfrak{m}^{*}$ into at most $\ll \log ^{3} X$ disjoint sets $E\left(Z_{1}, Z_{2}, y\right)$. For $\alpha \in E\left(Z_{1}, Z_{2}, y\right)$ we have

$$
Z_{1}<\left|S_{2}\left(\lambda_{1} \alpha\right)\right| \leqslant 2 Z_{1}, \quad Z_{2}<\left|S_{2}\left(\lambda_{2} \alpha\right)\right| \leqslant 2 Z_{2}, \quad y<|\alpha| \leqslant 2 y
$$

where $Z_{1}=2^{k_{1}} X^{7 / 16+2 \varepsilon}, Z_{2}=2^{k_{2}} X^{7 / 16+2 \varepsilon}$ and $y=2^{k_{3}} X^{-1 /(2 k)-\varepsilon}$ for some nonnegative integers $k_{1}, k_{2}, k_{3}$.

For simplicity, we take the notation $\mathscr{A}$ as a shortcut for $E\left(Z_{1}, Z_{2}, y\right)$, and let $m(\mathscr{A})$ denote the Lebesgue measure of $\mathscr{A}$.

Lemma 4.3. We have

$$
m(\mathscr{A}) \ll y X^{5 / 2+8 \varepsilon}\left(Z_{1} Z_{2}\right)^{-4} .
$$

Proof. See [17], Lemma 6.
By (2.2), the arithmetic-geometric mean inequality and Hölder's inequality, we have

$$
\begin{aligned}
I(\tau, \eta, \mathscr{A}) \ll & \sum_{j=3}^{4} \int_{\mathscr{A}}\left|S_{2}\left(\lambda_{1} \alpha\right) S_{2}\left(\lambda_{2} \alpha\right)\right|\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{2}\left|S_{k}(\mu \alpha)\right| K_{\tau}(\alpha) \mathrm{d} \alpha \\
\ll & \left(\int_{\mathscr{A}}\left|S_{2}\left(\lambda_{1} \alpha\right) S_{2}\left(\lambda_{2} \alpha\right)\right|^{4} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 / 4}\left(\int_{\mathbb{R}}\left|S_{k}(\mu \alpha)\right|^{\psi(k)} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 / \psi(k)} \\
& \times\left(\int_{\mathscr{A}} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 / 4-1 / \psi(k)} \sum_{j=3}^{4}\left(\int_{\mathbb{R}}\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{4} K_{\tau}(\alpha) \mathrm{d} \alpha\right)^{1 / 2} \\
\ll & \left(\left(Z_{1} Z_{2}\right)^{4} m(\mathscr{A}) \min \left(\tau^{2}, y^{-2}\right)\right)^{1 / 4}\left(\tau X^{\psi(k) / k-1+\varepsilon}\right)^{1 / \psi(k)} \\
& \times\left(\min \left(\tau^{2}, y^{-2}\right) m(\mathscr{A})\right)^{1 / 4-1 / \psi(k)}\left(\tau X^{1+\varepsilon}\right)^{1 / 2} \\
\ll & \tau^{1 / 2+1 / \psi(k)}\left(y \min \left(\tau^{2}, y^{-2}\right)\right)^{1 / 2-1 / \psi(k)} X^{7 / 8+1 / k+3 \varepsilon} \\
\ll & \tau X^{7 / 8+1 / k+3 \varepsilon} \ll \tau^{2} X^{1+1 / k-2 \varepsilon},
\end{aligned}
$$

where Lemmas 4.2-4.3 and the bounds $Z_{j} \geqslant X^{7 / 16+2 \varepsilon}(j=1,2)$ are used. Thus,

$$
\begin{equation*}
I\left(\tau, \eta, \mathfrak{m}^{*}\right) \ll\left(\log ^{3} X\right) \max _{\mathscr{A}}|I(\tau, \eta, \mathscr{A})| \ll \tau^{2} X^{1+1 / k-\varepsilon} \tag{4.10}
\end{equation*}
$$

It follows from (4.9) and (4.10) that

$$
\begin{equation*}
I(\tau, \eta, \mathfrak{m}) \ll \tau^{2} X^{1+1 / k-\varepsilon} . \tag{4.11}
\end{equation*}
$$

## 5. The trivial arcs

The proof of $|I(\tau, \eta, \mathfrak{t})| \ll \tau^{2} X^{1+1 / k-\varepsilon}$ is almost identical to that of inequality (25) in [17]. We list it for the sake of completeness.

$$
\begin{align*}
|I(\tau, \eta, \mathfrak{t})| & \ll \int_{\xi}^{\infty}\left|S_{2}\left(\lambda_{1} \alpha\right) S_{2}\left(\lambda_{2} \alpha\right) S_{2}\left(\lambda_{3} \alpha\right) S_{2}\left(\lambda_{4} \alpha\right) S_{k}(\mu \alpha)\right| K_{\tau}(\alpha) \mathrm{d} \alpha  \tag{5.1}\\
& \ll X^{1 / k} \sum_{j=1}^{4} \int_{\xi}^{\infty}\left|S_{2}\left(\lambda_{j} \alpha\right)\right|^{4} K_{\tau}(\alpha) \mathrm{d} \alpha \\
& \ll X^{1 / k} \sum_{j=1}^{4} \int_{\left|\lambda_{j}\right| \xi}^{\infty} \frac{\left|S_{2}(\alpha)\right|^{4}}{\alpha^{2}} \mathrm{~d} \alpha \\
& \ll X^{1 / k} \sum_{j=1}^{4} \sum_{n \geqslant\left|\lambda_{j}\right| \xi} \frac{1}{(n-1)^{2}} \int_{n-1}^{n}\left|S_{2}(\alpha)\right|^{4} \mathrm{~d} \alpha \\
& \ll \frac{X^{1 / k} X^{1+\varepsilon}}{\xi} \ll \tau^{2} X^{1+1 / k-\varepsilon} .
\end{align*}
$$

## 6. Completion of the proof

By (3.7), (4.11), (5.1) and (2.5), we get $I(\tau, \eta, \mathbb{R}) \gg \tau^{2} X^{1+1 / k}$. It follows from (2.4) that

$$
\mathcal{N}(X) \gg \tau X^{1+1 / k}(\log X)^{-5} \gg X^{1+1 / k-1 /(16 \vartheta(k))+\varepsilon}
$$

Recalling that $\lambda_{1} / \lambda_{2}$ is irrational, $q$ is a large enough denominator of a convergent to $\lambda_{1} / \lambda_{2}$ and $X=q^{2}$. When $q \rightarrow \infty$, we have $X \rightarrow \infty$; this implies $\mathcal{N}(X) \rightarrow \infty$. The value of $\tau$ and $\max p_{j} \asymp X^{1 / 2}$ give the desired range of $\sigma$ on the right-hand side of (1.1). This completes the proof of Theorem 1.2.

Acknowledgment. The authors are very grateful to the referee for many valuable suggestions.
